Chapter 1: Introduction

This report studies a vital financial derivative in today's markets, namely options. The popularity of options in today's market can easily be seen by the exponential growth in their trading volume from when standardized, exchange-traded stock options were first listed in The Chicago Board Options Exchange in 1973 [Mar02, p. 51-52] to 2022, shown in Figure 1.1. The option market is widely considered a venue for informed trading

1.1 Standard options

A standard option is a contract between two parties which gives the holder the right to buy (or sell) an asset for an agreed upon (exercise) price prior to, or on a determined (expiry) time in the future; regardless of the current (spot) price. Since the holder of the contract is not obliged to exercise the contract at the expiry time, they would not hold any liability in the absence of a price to purchase the option. The problem then becomes what is the correct price to charge the holder of the option to balance this inequality of liability.

1.2 Asian options

Whilst standard options, namely European and American style involve using the spot price as the underlying value of the asset; this is not always the case with exotic options. Exotic options differ in their payment structures, expiration dates, and/or strike prices. In the case of exotic fixed-strike price Asian style options the averaging price of the asset is used in place of the underlying asset. This differs from fixed-price Asian style options which instead use the averaging price of the asset to take place of the strike price. These are the two main variations of Asian style options but both of these can be varied further in how the averaging is calculated, for example: geometrically, arithmetically, average taken every day or average taken at the start of each month; and of course these can be varied further by having an expiry structure the same as a European option, or an American option.

1.3 A brief history of options
